

What Application do I want to recreate?

I want to recreate a communication application similar to Discord.

What Features do I want incorporated?

- Direct message system with ability to make group chats.
- Ability to add/create/delete servers (people can only delete the server if they are the owner of the server or have a specific authority within the server). These servers are like communities where people can interact with one another. These servers will tend to have a certain theme/ niche topic they like talking about, some servers don't need to have a specific niche or theme they can also be created by the users themselves and have a friend group within that server.
- To add a servers users must use an invite link provided by someone in that community/server
- Adding/removing/suggesting/blocking users
- Giving every user a specific skew code for their profile that distinguishes them from other users allowing for fun creative names. These skews will be held in the database that will be stored within the sessionMememory.

What tech stack do I want to use?

- HTML & CSS for styling and format
- Javascript for frontend
- Python & Flask for backend
- Use sessionMememory for database rather than implementing postgres

What are the restrictions/rules that have to be followed?

- Do not use any API keys UNLESS they are going to be free of charge.
- Must be accessible within laptop/browser/phone
- Must have comments regarding what data structure is being used within the code alongside an explanation of what the code is doing and how it interacts with the program
- DO NOT PUSH CODE unless I allow
- Create/update if README.md exist already as the project progresses and keep the README comprehensive, well-organized, and professionally formatted. Includes clear project description, detailed installation/usage instructions, and additional relevant information. Generated effectively with Copilot assistance.
- Application runs flawlessly with multiple interactive features that work as intended. Demonstrates ambitious scope and polished execution. Clear evidence of iterative development and problem-solving.
- Any sensitive information (e.g. API keys IF USED) go into .gitignore/.env
